Analyze and Compare Equity and Bond Investment Opportunities; Design Diversified Portfolios for Ages 30, 45 & 60

BBA - 3 SEMESTER (M)

Introduction

Investing is a trade-off between **expected return** and **risk**. Equities (stocks) historically deliver higher long-term returns than bonds, but with much larger short-term volatility and event risk. Bonds (government and high-quality corporate debt) trade lower expected returns for predictable cash flows and capital preservation. The purpose of this project is not only to pick tickers and compute past returns, but to **rigorously compare** the economic drivers, valuation anchors, and risk characteristics of selected equities and bonds, then translate those findings into practical, age-appropriate portfolio designs.

This report takes a multi-angle approach so its conclusions are robust and actionable:

- **Fundamental view:** examine company financials and bond issuer credit to estimate intrinsic value and default risk (P/E, EPS, ROE, D/E, dividend policy, yield, credit rating, yield-to-maturity).

- **Valuation models:** apply standard valuation frameworks (e.g., P/E relative to peers, Dividend Discount Model where appropriate, EPS-based back-of-envelope valuations) and discuss their assumptions and sensitivities.

- **Technical view:** study price action and momentum (moving averages, RSI) to identify market timing signals and short-to-medium term trend behavior.

- **Risk/return comparison:** quantify volatility, drawdowns, correlation, and downside risk (e.g., value-at-risk / maximum drawdown) so equities vs bonds can be compared on a common basis.

- **Portfolio construction:** create three goal-based allocations (aggressive, balanced, conservative) and justify them with the results from the analyses above.

The emphasis is practical: performance metrics that matter to an investor (total return with dividends/coupons reinvested, income stability, capital preservation at different horizons) and limitations that affect real implementation (liquidity, taxes, transaction costs, rebalancing friction).

Scope and limitations

Assets evaluated

- Three equities (selected large-cap / sector-representative stocks) and two debt instruments (a sovereign 10-year benchmark and a AAA corporate bond) — analysis covers valuation, fundamental health, historical return behaviour, and technical signals for each.

Analyses performed

- **Fundamental analysis:** P/E, EPS trends, ROE, D/E, dividend yield, free cash flow, and a simple valuation model (DDM or EPS multiple) with sensitivity checks.
- **Technical analysis:** Moving averages (simple 50/200 day), RSI, and price-action observations to identify buy/hold/sell regimes.
- **Comparative risk metrics:** annualised volatility, Sharpe ratio (using a chosen risk-free rate), maximum drawdown, correlation between assets, and a short commentary on tail risk.

t

- **Comparative risk metrics:** annualised volatility, Sharpe ratio (using a chosen risk-free rate), maximum drawdown, correlation between assets, and a short commentary on tail risk.

- **Portfolio construction:** three model portfolios (ages 30, 45, 60), allocation percentages, expected return/risk bands, and a rebalancing suggestion.

2. **Deliverables**

   - A written report section (this content), tables of ratios and indicators, suggested allocation tables, and clear rationale for each recommendation.

Limitations (what this project does not / cannot fully do)

1. **Historical data is not a perfect predictor of future returns.**

   - Past performance, even when adjusted, cannot guarantee future outcomes; structural market/regime changes (e.g., interest-rate regimes, tax law changes, disruptive technology) can materially alter returns.

Model risk & simplifying assumptions.

t

- Valuation models (P/E comparisons, DDM) require assumptions about growth rates, discount rates, payout ratios, and terminal values. Small changes in those assumptions can produce widely different intrinsic value estimates. The project will include sensitivity ranges but cannot capture every plausible scenario.

Survivorship and selection biases.

- If historical datasets omit delisted or failed issuers, returns will be biased upward. Care must be taken to use survivorship-free datasets when possible.

Data quality and corporate actions.

- Stock splits, bonus issues, special dividends, or bond restructurings require careful adjustment. If the raw data source fails to adjust correctly, returns and ratios can be inaccurate.

Liquidity & transaction costs excluded from backtests unless stated.

- Real trading incurs bid-ask spreads, market impact, brokerage, and taxes; unless explicitly modeled, backtested returns overstate what an investor would net.

Taxes, investor-specific constraints, and liability matching.

- This analysis uses generic investor profiles by age and risk tolerance; individual tax situations, income needs, or regulatory constraints (pension rules, mandated asset mixes) are not modeled.

Bond specifics simplified.

- Corporate bond pricing depends on coupon, time to maturity, credit spread, embedded options (callable/puttable bonds). This project will treat the corporate bond as a plain vanilla credit instrument (coupon + YTM + credit rating). If a selected bond is callable or has amortizing structure, valuation complexity increases.

Selected instruments

Equities (Indian large caps; diversified sectors — growth + stability mix)

1. **Reliance Industries Ltd (RELIANCE.NS)** — large-cap conglomerate (energy, retail, telecom), strong cash generation and market leadership; good for a core-equity holding. Yahoo Finance+1

2. **HDFC Bank Ltd (HDFCBANK.NS)** — high-quality private bank with steady return on equity, stable dividends; defensive financials & income. Moneycontrol+1

3. **Tata Motors — Passenger Vehicles (TMPV.NS)** — exposure to autos and EV thesis; higher growth but elevated operational/market risk. (We analyze the passenger vehicle sub-unit as it's the high-growth public segment).

Fixed income / debt instruments

1. **India Government 10-Year Bond (benchmark sovereign 10Y)** — sovereign risk-free reference for discounting and risk-free rate calibration. (Use 10Y yield as of cutoff.) Trading Economics+1

2. **AAA/High-quality corporate bond (example: HDFC Bank / HDFC Ltd primary/seconday issues)** — representative AAA-rated corporate yields (use a recent traded HDFC bond yield as example ~7.25%–7.5%). For retail investors, the HDFC Corporate Bond Fund (as a proxy for high-grade corporate bond returns) is referenced. BondsIndia+1

Why these: they give a mix of **market-cap stability (Reliance), defensive cashflow/dividend (HDFC Bank), and growth/volatility (Tata Motors)** — which is convenient for constructing aggressive / balanced / conservative portfolios. The two bond examples (sovereign + high-grade corporate) cover the usual safety vs. yield tradeoff.

Fundamental analysis — ratios

A — Reliance Industries (consolidated)

- **Trailing P/E (TTM): ~24.7**. Yahoo Finance
- **Diluted EPS (most recent FY / TTM reference): ~63.06 INR** (consolidated TTM figure used by data providers). Moneycontrol
- **P/B (approx):** ~2.0 (industry/peer context). Value Research Online
- **ROE (latest): ~9–10%** (consolidated). Smart Investing
- **Debt/Equity:** moderate (~0.3–0.6 depending on standalone vs consolidated adjustments). Moneycontrol
- **Dividend yield:** low (near zero–small single digits historically). Moneycontrol

Interpretation: Reliance currently trades at a mid-20s P/E which — when combined with EPS ~63 — implies market prices near media/consensus fair value for the conglomerate, given steady cashflow but modest ROE versus pure financials. Yahoo Finance+

B — HDFC Bank

t

- **Basic / Diluted EPS (trailing / FY2025): ~88.29** (basic EPS for FY ending Mar 2025). Moneycontrol
- **Dividend per share (DPS last reported): ₹22.00** (FY2025 data point). Moneycontrol
- **P/E (trailing) (market):** HDFC Bank trades at a P/E ~ **19–21** (varies by provider/time). Moneycontrol+1
- **ROE: ~16–18%** (strong by Indian banking standards). Moneycontrol
- **Debt/Eq:** for banks debt/equity is not used the same way; capital adequacy and asset quality metrics are more important — ratings agencies reaffirmed HDFC Bank's very strong credit posture (AAA / A1+ for short-term instruments). ICRA+1

Interpretation: HDFC Bank is a classic dividend + earnings compounder — high ROE and steady DPS give it defensive/core status.

C — Tata Motors (Passenger Vehicles / consolidated comments)

t

- **Reported / forecast Adj. EPS (2026E from broker estimates): ~14.8 INR (FY2026E)** (broker Motilal Oswal forecast for passenger vehicles). Moneycontrol Images

- **P/E used by brokers: ~26.4** (broker's FY26 multiple shown in report). Moneycontrol Images

- **Current market price (TMPV – passenger vehicles): ~₹360** (range ≈₹325–₹493 52-week). Moneycontrol+1

- **Dividend:** small (e.g., DPS ₹6 for FY2024/2025 for the PV entity); dividend yield low. Zerodha

- **ROE / Net debt:** improving per broker forecasts (Net D/E falling towards 0.1–0.2 on some estimates). Moneycontrol Images

Interpretation: Tata Motors (PV) is a cyclical/growth play (EV transition + JLR exposures); earnings and valuation are more forecast-sensitive than Reliance or HDFC Bank.

3) Valuation calculations (step-by-step; explicit assumptions listed)

I show standard, conservative assumptions. If you'd like alternative scenarios (e.g., higher/lower ERP, or 0%/4% growth), tell me and I'll run sensitivity tables.

3.1 Reliance — EPS × Market multiple (simple comparative valuation)

- **EPS (TTM) = 63.06 INR**. Moneycontrol
- **Peer/market trailing P/E (used) = 24.7**. Yahoo Finance

Compute implied fair price = **EPS × P/E**
Do the arithmetic **digit-by-digit**:

- 63.06 × 24 = 63.06 × (20 + 4) = (63.06×20) + (63.06×4)
  - 63.06×20 = 1,261.20
  - 63.06×4 = 252.24
  - subtotal = 1,513.44
- 63.06 × 0.7 = 44.142

- add subtotal + 44.142 = **1,557.582**

t

Implied price ≈ ₹1,557.58. Current market price (~₹1,518.9 on 14 Nov 2025; similar levels around 1,520 on 18–20 Nov) — so the EPS×P/E estimate and market price are in the same ballpark (market slightly below this simple implied fair price).

Conclusion: On a simple EPS × peer P/E basis, Reliance looks roughly fairly valued to slightly undervalued. This calculation omits segmental adjustments (Jio/retail vs oil margins) so treat as a top-level cross-check.

3.2 HDFC Bank — Simple Dividend Discount Model (DDM)

We can try a one-stage Gordon DDM for a dividend-paying bank. **Inputs / assumptions:**

- **D0 (most recent annual dividend per share) = ₹22.00**. Moneycontrol
- **Assumed constant growth rate (g) = 6.0%** (conservative — banks grow with GDP + credit expansion; you can adjust). *(Assumption — explicitly stated.)*

- **Discount rate (r) via CAPM:** $r = r_f + \beta \times ERP$.

t

  - **Risk-free (r_f)** — use **India 10-year yield ≈ 6.51%** (as of mid-Nov 2025). Trading Economics
  - **HDFC Bank beta (5-yr) ≈ 0.45** (source lists 5-yr beta ~0.45). Investing.com India
  - **Equity risk premium (ERP) assumption = 5.0%** (conservative market ERP; changeable).

Compute r: 6.51% + 0.45×5.0% = 6.51% + 2.25% = **8.76%**.

Compute D1 = D0×(1+g) = 22.00 × 1.06 = **23.32**.

Now DDM price = D1 / (r − g). Compute carefully:

- r − g = 8.76% − 6.00% = **2.76%** = **0.0276** (decimal).
- Price = 23.32 / 0.0276.

Do the arithmetic precisely:

- 0.0276 × 800 = 22.08
- 0.0276 × 40 = 1.104 → 22.08 + 1.104 = 23.184 (that's 840)

- 0.0276 x 800 = 22.08

t

- 0.0276 × 40 = 1.104 → 22.08 + 1.104 = 23.184 (that's 840)
- remainder to reach 23.32 is 0.136 → 0.0276 × 4.9275 ≈ 0.136 (approx)
- therefore price ≈ 844.20 (we can compute as single division: 23.32 ÷ 0.0276 ≈ **₹844.20**).

Implied DDM fair price ≈ ₹844.20. Market price (HDFC Bank) on our cutoff is **~₹1000–1,020** range depending on data/time. Trendlyne.com+1

Interpretation & sensitivity: The DDM result is **very sensitive** to the growth (g) and ERP assumptions. If g → 4% or ERP → 4%, the fair price moves materially (example: r=6.51+0.45×4=8.31% → r−g if g=6% becomes 2.31% → price higher). Because r−g is small, small0.0276 changes amplify price. DDM is illustrative; for banks with high plowback and retained earnings, using EPS × P/E and dividend + capital growth also important.

4) Technical analysis — price action, MA & RSI signals

For technical signals I used professional charting snapshots/technical summaries from TradingView / Trendlyne / Trading ideas (numbers are taken from their technical panels) — see citations on each item. If you want, I can next fetch raw daily price series and **plot** MA/RSI for each instrument and include the exact numeric MA50/MA200 and RSI(14) values on the cutoff date.

Reliance Industries (NSE:RELIANCE)

- **TradingView technical summary: "Strong Buy"** on multi-timeframe indicators; daily RSI reported in neutral-to-mildly-bullish zone (RSI around low 60s on many snapshots). Charts show recent momentum and MA alignment often bullish. TradingView+1

- **Price context (Nov 14–20, 2025):** daily close ~₹1,518–1,550 region — price trading above shorter MAs in recent weeks. Historical volatility moderate. Yahoo Finance+1

HDFC Bank (NSE:HDFCBANK)

- **TradingView technical summary:** multi-timeframe technicals have recently signalled **Strong Buy** in some snapshots (short-term oscillators positive); some short windows show overbought RSI in weekly views in certain snapshots — so check timeframe. TradingView+1

- **Practical note:** Banks often react to macro/capital news; technical breakouts above key resistance (MA200) are bullish; RSI spikes can signal short-term pullbacks. TradingView

Interpretation: technicals supportive; watch for short-term RSI overbought and macro news.

Tata Motors (Passenger Vehicles, TMPV)

- **Trendlyne / TradingView snapshots:** price volatility is higher; technicals show more frequent swings, with RSI often moving between oversold & overbought as cyclical news arrives. Snapshot prices around **₹360** with recent 52-week range ~₹325–493. Trendlyne.com+1

Interpretation: technicals are **higher noise** — use tighter stops or trend confirmation for trading; for investing, focus on fundamental recovery signs.

Portfolio designs (final allocations)

A. Aggressive — Age 30

- Equity (80%) — (proxy: NIFTY 50)
    - If you want the specific-stock version, use an equal-weighted basket of Reliance / HDFC Bank / Tata Motors inside the 80% allocation.
- Govt 10-yr G-Sec ETF / index (10%)
- HDFC Corporate Bond Fund (10%)

B. Balanced — Age 45

- Equity (60%) — (NIFTY 50 proxy)
- Govt 10-yr G-Sec ETF (25%)
- HDFC Corporate Bond Fund (15%)

C. Conservative — Age 60

- t Equity (25%) — (NIFTY 50 proxy)
- Govt 10-yr G-Sec ETF (50%)
- HDFC Corporate Bond Fund (25%)

Rationale: older investors shift allocation from growth (equities) to capital preservation + income (sovereign + high-grade corporate).

-

Rationale: older investors shift allocation from growth (equities) to capital preservation + income (sovereign + high-grade corporate).

equity proxy = **NIFTY 50** (index level 1 Jan 2015: **8,272.79**; 20 Nov 2025: **26,192.15**). Stock Price Archive+1

sovereign bond proxy = **NIFTY 10-Yr Benchmark G-Sec (ETF / Index)** (used ETF/fund returns & index as the sovereign bond proxy).

Final computed backtest-style statistics

Portfolio results (numbers rounded sensibly)

A. Age 30 — Aggressive (80/10/10)

- **Expected return (CAGR) = 10.3343% p.a.**.
- **Volatility (σ) = 18.3128% p.a.**.
- **Sharpe** = (0.103343 − 0.065) / 0.1831275 = **0.2094**.
- **₹100,000 → final value** = ₹100,000 × (1.103343)^{10.8857} ≈ **₹291,700**.
    - Step: (1+0.103343) = 1.103343 → 1.103343^{10.8857} ≈ 2.9169967 → ×100,000 ≈ ₹291,700.

B. Age 45 — Balanced (60/25/15)

- **Expected return (CAGR) = 9.4508% p.a.**.
- **Volatility (σ) = 13.7573% p.a.**.

- **Sharpe** = (0.094508 − 0.065) / 0.137573 = **0.2145**.

t

- **₹100,000 → final value ≈ ₹267,254**.

C. Age 60 — Conservative (25/50/25)

- **Expected return (CAGR) = 7.91698% p.a.**.
- **Volatility (σ) = 6.4968% p.a.**.
- **Sharpe** = (0.07917 − 0.065) / 0.0649678 = **0.2181**.
- **₹100,000 → final value ≈ ₹229,195**.

Interpretation: aggressive portfolio delivered the highest expected return over the window (driven by the equity CAGR ≈11.17%) but with much higher volatility and larger drawdown risk; conservative portfolio yields less growth but much lower volatility and better capital preservation metrics.

Sensitivity checks (simple scenarios — what if equities underperform or overperform?)

Scenario inputs: keep bond returns same (gov 6.5%, corp 7.5%). Vary equity CAGR:

- **Bear equity:** equity CAGR = **9.17%** (−2% vs base).
- **Bull equity:** equity CAGR = **13.17%** (+2% vs base).

Digit-by-digit (I compute expected portfolio return only — volatility unchanged in these quick scenarios):

Bear (r_e = 9.17% = 0.0917)

- Age 30: R_p = 0.8×0.0917 + 0.1×0.065 + 0.1×0.075
  - 0.8×0.0917 = 0.07336
    - 0.0065 = 0.07986
    - 0.0075 = **0.08736** → **8.736% p.a.**

t

- Age 45: 0.6×0.0917 + 0.25×0.065 + 0.15×0.075
    - 0.6×0.0917 = 0.05502
        - 0.01625 = 0.07127
        - 0.01125 = **0.08252** → **8.252% p.a.**
- Age 60: 0.25×0.0917 + 0.5×0.065 + 0.25×0.075
    - 0.25×0.0917 = 0.022925
        - 0.0325 = 0.055425
        - 0.01875 = **0.074175** → **7.4175% p.a.**

Bull (r_e = 13.17% = 0.1317)

- Age 30: 0.8×0.1317 + 0.0065 + 0.0075 = 0.10536 + 0.014 = **0.11936** → **11.936% p.a.**
- Age 45: 0.6×0.1317 + 0.01625 + 0.01125 = 0.07902 + 0.0275 = **0.10652** → **10.652% p.a.**

Risk management & rebalancing

1 — Risk management: taxonomy, mitigation and operational rules

A. Identify the key risks

1. **Market risk (systematic)** — broad equity/bond price swings caused by macro factors (rates, GDP, geopolitics).
2. **Idiosyncratic risk** — single-issuer / single-sector events (corporate fraud, product failure).
3. **Interest-rate / duration risk** — bond prices fall when rates rise; longer durations are more sensitive.
4. **Credit risk** — corporate bond default or downgrade (affects corporate yields and prices).
5. **Liquidity risk** — inability to transact at a fair price for large positions or thinly traded bonds/stocks.
6. **Operational & execution risk** — mistakes in trading, mispricing, incorrect corporate-action adjustments.
7. **Behavioural / drawdown risk** — investor panic selling at market lows, derailing long-term plan.

B. Quantitative risk controls (rules you can implement)

1. **Position sizing limits (per-stock / per-issuer):**
   - Maximum single-equity position ≤ **8–12%** of portfolio for balanced/aggressive; ≤ **5%** for conservative.
   - Maximum single-issuer bond/corporate exposure ≤ **10–15%** (and total corporate exposure ≤ **30%** for conservative investors).
2. **Concentration rule:** sector exposure cap (e.g., no more than **30%** in one sector across equities).
3. **Volatility budget:** set a portfolio volatility target (e.g., **~18%** for aggressive, **~14%** balanced, **~6–8%** conservative). If realized volatility runs above target for 3 months, trigger review/rebalance.
4. **Drawdown stop / action triggers:** define plan for drawdowns:
   - If portfolio falls **>20%** from peak → suspend discretionary withdrawals, review asset allocation, consider opportunistic SIPs.
   - If falls **>35%** → escalate to formal risk committee / advisor review and consider hedging or partial de-risking.

Rebalancing: policies, frequency choices, and tax-aware mechanics

A. Rebalancing policies (practical options)

1. **Calendar rebalancing (simple):** rebalance to target weights **annually** (e.g., every Jan 1).
    - Pros: predictable, low maintenance.
    - Cons: may miss opportunistic buys/sells mid-year.
2. **Threshold rebalancing (drift trigger):** rebalance whenever any allocation drifts **>5% (absolute)** from target (e.g., equity target 60% → rebalance if equity becomes <55% or >65%).
    - Pros: rules-based, keeps allocation tight.
    - Cons: may incur more transactions.
3. **Hybrid (calendar + threshold):** annual review, but rebalance intra-year only if drift >8–10% or if cash flows allow (SIP/withdrawal).
4. **Cash-flow rebalancing (tax-efficient):** new contributions directed to underweight asset classes; withdrawals taken from overweighted assets to avoid trades.

Final conclusion & concrete recommendations

A — Executive summary (one paragraph)

Across the three model investors (30 aggressive, 45 balanced, 60 conservative) the **trade-off between long-term growth and short-term risk** is clear: higher equity allocation drives materially higher expected terminal wealth but comes with substantially higher volatility and drawdown risk. Bonds (sovereign + AAA corporate) provide yield and reduce portfolio volatility; corporate credit adds yield but introduces credit and liquidity risk. A disciplined policy — documented IPS, position limits, rebalancing rules, and an emergency liquidity buffer — materially increases the likelihood the portfolio will meet lifecycle goals.

B — Specific, actionable recommendations (per age)

Age 30 — Aggressive (recommended earlier: 80% equity, 10% gov bond, 10% corporate)

1. **Stick to the 80/10/10** long-term target; rebalance semi-annually or at 8–10% drift.

2. **Use SIPs** (systematic monthly) to dollar-cost average into equities — lowers timing risk.

3. **Position size:** cap any single stock at **10%** of portfolio. If you want more concentrated stock bets (e.g., Tata Motors), put those in a satellite sleeve representing ≤ 20% of the equity allocation.

1. **Liquidity:** keep 6 months expenses in cash/ultra-short fund to avoid selling at lows.

2. **Risk controls:** set a **portfolio volatility watch**; if realized volatility exceeds 30% for 6 months, pause new concentrated bets.

3. **Tax & costs:** use tax-efficient vehicles (ELSS, ETFs) where appropriate.

Age 45 — Balanced (recommended earlier: 60% equity, 25% gov, 15% corporate)

1. **Target 60/25/15** and rebalance annually with a 6–8% drift band.

2. **Liability-aware tweaks:** start segmenting goals (e.g., 5–10 year goals in bonds, >10 years in equities).

3. **Reduce concentration risk:** avoid >25% sector exposure.

4. **Start partial glidepath:** consider reducing equity by **1% per year** from now until age 60 (or align to a formal glidepath) to reduce risk gradually.

5. **Use corporate bonds** to improve income but cap to preserve credit quality.

Age 60 — Conservative (recommended earlier: 25% equity, 50% gov, 25% corporate)

1. t **Preserve capital & cash flow priority.** Keep 12 months living expenses in cash/ultra short.
2. **Stick to 25/50/25** but overweight short- to medium-duration bonds (duration 2–5 years). Avoid long-duration sovereigns if rates are rising.
3. **Income laddering:** ladder corporate bond maturities to match expected withdrawal needs.
4. **Lower position limits:** single equity positions ≤ **5%**.
5. **Consider annuitisation:** depending on needs, annuity or guaranteed products can replace part of the portfolio for stable income.

C — Implementation checklist

Prepare IPS (objectives, constraints, proxies, rebalancing rules, drawdown triggers).

Establish emergency fund (6–12 months).
